Bibliography

Foreword

If a piece of software or an e-book can be made completely open source, why not a notebook?

This brings me back to the summer of year 2009, when I just started my third year as a high school student in Harbin No. 3 High School. In around August and September of every year, that is, when the results of Gaokao (National College Entrance Examination of China, annually held in July) are released, people from photocopy shops will start selling notebooks photocopies that they claim to be of the top scorers of the exam. Much as I was curious about what these notebooks look like, I myself did not expect to actually learn anything from them, mainly for the following three reasons.

First of all, some (in fact many) of these notebooks were more tough to understand than the textbooks. I guess we cannot blame the top scorers for being too smart and making things sometimes extremely brief or overwhelmingly complicated.

Secondly, why would I wanted to adapt to notebooks of others when I had my own, which should be as good as theirs.

And lastly, as a student in the top high school myself, I knew that the top scorers of the coming year would probably be a schoolmate or a classmate. Why would I want to pay that much money to a complete stranger in a photocopy shop for my friend's notebook, rather than asked from him or her directly?

However, things had changed after my becoming an undergraduate student in year 2010. Since in the university there were so many modules and materials to learn, students were often distracted from digging into one book or module very deeply. (For those who were still able to do so, you have my highest respect.) The situation got even worse as I became a Ph.D. student in year 2014, this time due to that I had to focus on one research topic entirely, and could hardly split much time on other irrelevant but still important and interesting contents.

This motivated me to start reading and taking notebooks for selected books and articles such as journal papers and magazines, just to force myself to spent time learning new subjects. I usually used hand-written notebooks. My very first notebook was on *Numerical Analysis*, an entrance level module for engineering background graduate students. Till today I have on my hand dozens of notebooks, and one day it suddenly came to me: why not digitalize them, and make them accessible online and open source, and let everyone read and edit it?

viii Foreword

As majority of open source software, this notebook (and it applies to the other notebooks in this series) does not come with any "warranty" of any kind, meaning that there is no guarantee for the statement and knowledge in this notebook to be exactly correct as it is not peer reviewed. **Do NOT cite this notebook in your academic research paper or book!** Of course, if you find anything here useful with your research, feel free to trace back to the origin of the citation, and double confirm it yourself then on top of that determine whether or not to use it in your research.

This notebook is suitable as:

- a quick reference guide;
- a brief introduction for beginners of the module;
- a "cheat sheet" for students to prepare for the exam (Don't bring it to the exam unless it is allowed by your lecture!) or for lectures to prepare the teaching materials.

This notebook is NOT suitable as:

- a direct research reference;
- a replacement to the textbook;

because as explained the notebook is NOT peer reviewed and it is meant to be simple and easy to read. It is not necessary brief, but all the tedious explanation and derivation, if any, shall be "fold into appendix" and a reader can easily skip those things without any interruption to the reading.

Although this notebook is open source, the reference materials of this notebook, including textbooks, journal papers, conference proceedings, etc., may not be open source. Very likely many of these reference materials are licensed or copyrighted. Please legitimately access these materials and properly use them if necessary.

Some of the figures in this notebook is drawn using Excalidraw, a very interesting tool for machine to emulate hand-writing. The Excalidraw project can be found in GitHub, excalidraw/excalidraw.

Preface

Some references of this notebook are the Linux Bible (10th edition) that I borrowed from National Library Singapore, and also many Bilibili and YouTube videos, which I will cite as I go through the notebook.

Part I Linux Basics

General Introduction to Linux

CONTENTS

1.1	Brief Introduction to Linux	3
1.2	A Short History of Linux	4

This chapter gives a brief introduction Linux, including some of its key features and advantages/disadvantages over other operating systems.

1.1 Brief Introduction to Linux

Linux is an operating system. An operating system is essentially a special piece of software running on a computer (or servers, or mobile devices, or any other electrical device that is complicated enough and requires an operating system) that manages hardware resources of the system and provide services to the upper application layer software. To be more precise, an operating system shall be able to

- detect and prepare hardware;
- manage processes;
- manage memory;
- provide user interface and user authentication;
- manage file systems;
- provide programming tools for creating applications.

Linux has been overwhelmingly successful and has been adopted in many different areas. For example, Android operating system for mobile phones is developed using Linux. Google Chrome is also backed by a Linux operating system. Many famous websites including Facebook are also running on Linux servers.

Some of the most favorable features of Linux (especially to large size enterprises) are as follows.

- Clustering: multiple sets of hardware appearing to be one computer.
- Visualization: different hosts running on the same hardware set, each of which appears to be on a separate computer with specialized features.
- Cloud computing: flexible resources management realized by running applications on cloud on virtual Linux computer.
- Real-time computing: embedded Linux based microcontrollers or computers.

Linux differs from Microsoft Windows and MacOS in many ways, though they are all very good operating systems. Among the three operating systems, Linux is the only one that is completely open source (in the sense that all its code can be viewed and modified per requested), thus adding a lot of flexibility when using it.

1.2 A Short History of Linux

The initial motivation of Linux is to create a UNIX-like operating system that can be freely distributed in the community.

Many modern computer systems including MacOS and Linux are derived from UNIX. UNIX operating system was created by AT&T in 1969 as a better software development environment that AT&T used internally. In 1973, UNIX was rewritten in C language, thus adding more useful features such as portability. Today, C is still the primary language used to create UNIX (and also Linux) kernels.

AT&T, who originally owned UNIX, tried to make UNIX into a commercial product. However, back then AT&T was restricted from selling computers. Therefore, AT&T decided to license UNIX source code to universities for a nominal fee. Researchers from universities start learning and improving UNIX, which speed up the development of UNIX. In 1976, UNIX V6 became the first UNIX that was widely spread. UNIX V6 is developed at UC Berkeley and was named the Berkeley Software Distribution (BSD). From then on, UNIX moved towards two separate directions: BSD continued forward in the "open" and "share" manner, while AT&T started steering UNIX toward commercialization and by 1984 AT&T was pretty ready to start selling UNIX (i.e. the commercialized version is mostly famous by the name "AT&T: UNIX System Laboratories (USL)"). USL did not sell very well. As said, AT&T could only sell source but not complete boxes of PC, and for this reason the price for the source code had to be higher than other OS (such as Microsoft Windows). Other companies, such as SCO and Sun Microsystems, were more successful sellers by selling UNIX based PC and workstations for high-end users. Overall, UNIX source code was extremely expensive.

In 1984, Richard Stallman started the GNU project as part of the Free Software Foundation. I is recursively named by phrase "GNU is Not UNIX", intended to become a recording of entire UNIX that could be open and freely distributed. The community started to "recreate" UNIX based on the defined interface protocols published by AT&T. The BSD got a good chance initially, it eventually failed due to the doubts people held for open source codes.

Linus Trovalds started creating his version of UNIX, i.e. Linux, in 1991. He managed to publish the first version of the Linux kernel on August 25, 1991, initially only worked for 386 processor. Later in October, Linux 0.0.2 was released with many parts of the code rewritten in C language, making it more suitable for cross-platform usage. This Linux kernel was the last and the most important piece of code to complete a UNIX-like system under GPL. It is so important that people call this operating system "Linux OS" instead of "GNU OS", although is the host of the project and Linux kernel is only a (most important) part of it.

As casual Linux users, people do not want to understand and compile the Linux source code to use Linux. To respond to this need, different Linux distributions have merged. They share the same OS kernel, but present themselves differently in many ways, for example in the way they manage software applications or design user interfaces. Today, there are hundreds of Linux distributions in the community. Two famous distributions in the community (and their variations) are listed below.

- Red Hat Distribution
 - Red Hat Enterprise Linux (RHEL)
 - Fedora
 - CentOS
- Debian Distribution
 - Ubuntu
 - Linux Mint
 - Elementary OS
 - Raspberry Pi OS

4.1 Text File Editing Environment in Linux

"nobreak

4.2 Vim

Vim is a free and open-source software initially developed by Bram Moolennar, and has become the default text editor of many Unix/Linux based operating systems.

Some people claim *Vim* to be the most powerful text file editor as well as integrated development environment for programming on a Linux machine (and potentially on all computers and servers). The main reasons are as follows.

- *Vim* is usually built-in to Linux during the operating system installation, making it the most available and cost-effective text editor.
- Vim can work on machines where graphical desktop is not supported.

[&]quot;nobreak

- Vim is light in size and is suitable to run even on an embedded system.
- Vim operations are done mostly via mode switch and shortcut keys, so that the brain does not need to halt and wait for the hand to grab and move the mouse which slows down the text editing and interrupts the logic flow.
- Vim is highly flexible and can be customized according to the user's habit (for example, through ~/.vim/vimrc), and it allows the users to define shortcut keys.
- Vim can automate repetitive operations, such as by using macros.
- Vim can be integrated with third-party tools for useful functions such as browsing project folders.

The above reasons have their point, and it is true Vim can be come very powerful and convenient for the user if he is very familiar with it and is very used to it. On the other hand, however, Vim is not as intuitive as other text editors such as gedit and notepad++, and may require a learning curve for beginners.

In this section, *Vim* is introduced as the text editor that will be used for viewing and editing text files, either being configuration files or programming codes.

4.2.1 General Introduction to Vim

Different from other text editors, Vim defines different "modes" during the operation, each mode has some unique features. For example, in the insert mode, Vim takes in the keyboard inputs and put them into the text file. In this concept, many other editors can be taken as a slim version of Vim where there is only one mode, the insert mode.

In the case of *Vim*, however, there are other equally useful modes that eventually make it unique and powerful. For example, in the *normal* mode (this is the default mode when opening *Vim*), *Vim* uses useful and customizable shortcut keys to quickly navigate the document and perform operations such as cut, copy, paste, replace, search, and macro functions. In the *virtual* mode, *Vim* allows the user to select partial of the document for further editing. In the *cmdline* mode, *Vim* takes order from command lines and interact with Linux to perform tasks such as save, quit or even navigating folders.

The following Table 4.1 summarizes the commonly used modes in Vim.

As a start, the following basic commands can be used to quickly create, edit and save a text file using vim. In home directory, start a shell and key in

\$ vim testvim

to create a file named "testvim" and open the file using Vim. Notice that in some Linux versions, vi might be aliased to vim by default.

TABLE 4.1

Commonly	used modes in Vim.
Mode	Description
Normal	Default mode. It is used to navigate the cursor in the text, search
	and replace text pieces, and run basic text operations such as
	undo, redo, cut (delete), copy and paste.

Insert It is used to insert keyboard inputs into the text, just like commonly used text editors today.

Visual It is similar to normal mode but areas of text can be highlighted.

Normal mode commands can be used on the highlighted text.

Cmdline It takes in a single line command input and perform actions accordingly, such as save and quit.

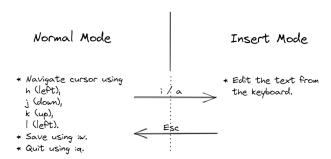

FIGURE 4.1

Mode switching between normal mode and insert mode, and basic functions associated with the modes.

The above basic commands and their relationships are summarized in Fig. 4.1. A flowchart to create/open, edit, save, and quit a text file using the aforementioned commands are given in Fig. 4.2.

4.2.2 Configure Customizable User Profile

With the basic operations introduced in Section 4.2.1, we are able to create and edit a text file as we want to, just like using any other text editor. Though at this point the advantages of using *Vim* over other text editors are not obvious yet, the *Vim* editor is finally useful now.

Before introducing more advanced features of Vim for more convenient

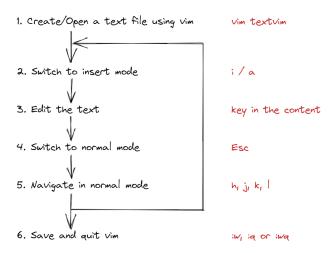

FIGURE 4.2

A flowchart for simple creating, editing and saving of a text file using Vim.

user experience, we can now customize user profile to suit our individual habit. Notice that the customization is completely optional and personal. This section only introduces the ideas and basic methods of such customization, such as re-mapping keys and create user-defined shortcuts. Everything introduced here are merely examples and it is completely up to the user how to design and implement his own profile.

In Linux, navigate to home directory. Create the following path and file "/.vim/vimrc or "/.vimrc. Open the *vimrc* file as a blank file using *Vim*. The individual user profile can be customized here.

Mapping of Keys

It is desirable to re-map some keys to speed up editing. For example, people may want to map jj to Esc in insert mode for more convenient mode switching to normal mode (consequent "jj" is rarely used in English). Other people may feel like mapping j, k, i to h, j, k respectively in normal and visual modes, making the navigation more intuitive. In that case, a different key needs to be mapped for i since it is an important key for switching to insert mode.

It is possible re-map certain key (or keys combination) in selected modes. The following configuration in vimrc file re-maps the aforementioned keys.

```
inoremap jj <Esc>
noremap j h
noremap J H
```

```
noremap k j
noremap K J
noremap i k
noremap I K
noremap h i
noremap H I
```

where inoremap is used to map keys (combinations) in insert mode, and noremap in normal and visual modes.

The upper case letter S and lower case letter —s— in control mode are originally used to delete and substitute texts. They may be not so important in practice as there functions are overlapped by another shortcut key c, which is powerful in replacing characters and is more frequently used. We can re-map S for saving the text, and disable s to prevent mis-touching. Similarly, upper case letter Q is mapped to quit Vim.

```
noremap s <nop>
map S :w<CR>
map Q :q<CR>
```

where <nop> stands for "no operation" and CR stands for the "enter" key on the keyboard. The keyword map differs from noremap in the sense that map is for recursive mapping.

Syntax Highlight, Color Scheme and Others

By default *Vim* displays white color contents on black background. Use the following command in *vimrc* to enable syntax highlighting or change color scheme. Use :colorscheme in normal mode in *Vim* to check for available color schemes.

```
syntax on
colorscheme default
```

The following command displays the row index and cursor line (a underline at cursor position) of the text, which can become handy during the programming. Furthermore, it sets auto-wrap of text when a single row is longer than the displaying screen.

```
set number
set cursorline
set wrap
```

The following command opens a "menu" when using cmdline mode, making it easier to key in commands.

```
set wildmenu
```

Many users in the community have posted their recommended *Vim* user profile configuration online, such as on *GitHub*. For the convenience of the reader, in the rest of the notebook, we will assume that **no re-map of keys combinations or shortcuts** are implemented, when introducing the commands.

Notice that the configurations introduced in this section can also be activated with the *Vim* already started. Simply type: to switch from normal mode to cmdline mode, then key in the configuration. For example, :syntax on to activate the syntax display.

4.2.3 Commonly Used Operations in Normal Mode

The operations, such as delete, cut, copy, paste, replace and search, are mostly done in normal mode through shortcut keys. For example, dd delete (cut) the entire row at the cursor and p paste the row to its new position. For beginners, remembering shortcut keys can be difficult. In such case, it is recommended for us to look for the consistent patterns of the different commands, instead of brute-force remembering the keys only.

Many *Vim* shortcut keys in normal mode has the following structure, i.e. an operator command followed by a motion command, as shown below.

<operator><motion>

The operator command tells *Vim* what to do (say, copy), and the motion command tells the applicable range of the operation (say, the entire row, or the single word, or the single character, of the cursor position). Of course for some operator commands, they can be used alone without the motion command.

Delete/Cut, Change, Copy and Paste

We will use the most commonly used operator commands, delete/cut, change, copy (also known as "yank" in Vim) and paste to demonstrate the above idea.

In this demonstration, we will be editing the following lines taken from Wikipedia under "William Shakespeare". In the text file, each sentence takes a new row as given by Figure 4.3.

William Shakespeare (bapt. 26 April 1564 – 23 April 1616) was an English playwright, poet and actor, widely regarded as the greatest writer in the English language and the world's greatest dramatist.

He is often called England's national poet and the "Bard of Avon" (or simply "the Bard").

To quickly delete/cut a single character, use either x or X. Each time x is input in normal mode, it deletes the current cursor selected character, and automatically select the next character in the text. Each time X is input in

```
1 Milliam Shakespeare (bapt. 26 April 1564 - 23 April 1616) was an English playwright, poet and actor, widely regarded as the greatest writer in the English language and the world's greatest dramatist.
2 He is often called England's national poet and the "Bard of Avon" (or simply "the Bard").
```

FIGURE 4.3

A piece of text of "William Shakespeare", for demonstration.

normal mode, it keeps the current cursor selected character while deleting the previous character in front of the cursor. In this sense, x and X play like delete and backspace respectively in other text editors such as notepad++.

Operators x and X do not require consequent motion command, as they simply delete/cut one character immediately each time they are pressed. What if you want to delete multiple characters from the cursor? You can press x or X multiple times, or alternatively you can ask Vim to "emulate" doing that for you, as long as you tell Vim what actions (key combinations) and how many times you want perform. For example, 20x is equivalent with physically pressing x for 20 times. The same applies for other operators or motions commands. For example, 101 is equivalent of pressing 1 for 10 times, making the navigation faster.

Operator d does similar things as x and X but requiring a motion command, for more flexible usage. The motion shall tell *Vim* what to delete/cut.

For example, d1 deletes to the right, i.e. deletes the current cursor selected character, and automatically select the next character. It is the same as if \mathbf{x} is pressed. Similarly, dh deletes to the left, just like \mathbf{X} . What if you want to delete 20 characters to the right? You can key in d1 for 20 times. Or alternatively, just like the case for \mathbf{x} , you can tell Vim to do it by using 20d1. Or, you can change the motion, by using d201, where "201" as a whole plays as the motion of "to the right for 20 characters". Or, you can do a combination by using things like 5d41, since $20 = 5 \times 4$. All of the above gives you the same result (they will be a difference in the clipboard if later you want to paste them).

Thanks to the "operator-motion" structure, d can be used even more flexibly. For example, by using word-related motions, d can delete/cut by words instead of by characters. Move the cursor to the beginning of a word, (for example, "S" in "Shakespeare"), use dw to delete the word. The word motion w is similar with 1, except that 1 directs to the next character, while w directs to the beginning character of next word. Motion w can also be used to navigate in the text. Similarly, b directs to the beginning character of the current word (if the cursor is at the middle of the current word) or previous word (if the cursor is already at the beginning of the current word). Thus, db can be used to delete word to the left. You can use something like d10b, 10db, d20w, 5d4w to delete multiple words at a time.

When in the middle of a word, dw will delete the characters from the current cursor position till the beginning character of the next word. For example, if the cursor is currently at "k" in "Shakespeare", dw will delete

TABLE 4.2 Commonly used operators related to delete/cut, change, copy and paste.

Operator	Description
x	Delete/Cut the character at cursor.
- X	Delete/Cut the character before cursor.
dd	Delete/Cut the entire row.
d	Delete/Cut selected text according to the motion command.
cc	Change the entire row.
c	Change selected text according to the motion command.
уу	Copy the entire row.
у	Copy selected text according to the motion command.
<u>p</u>	Paste clipboard to the cursor.

"kespeare" (notice that the space between "Shakespeare" and "(bapt." will also be deleted). To delete from the beginning of the word instead of from the middle of the word, you can use b first to navigate back to the beginning of the word. Alternatively, use "inner-word" motion iw to indicate that you want to delete inner word. When the cursor is at "k" in "Shakespeare", use diw to delete the entire word.

So far we have introduced the delete/cut operator d, and character motion h (left), 1 (right), and also word motion b (left), w (right). There are similar motions for sentence ((previous),) (next) and paragraph { (previous), } (next). Finally, there is the inner-word motion iw to indicate the current word of cursor, whichever the cursor is inside the word. Similarly, there are innersentence motion is and inner-paragraph motion ip. There are also inner-quotation motion i', i", i' and inner-block motion i(, i<, i{, and many more. For example, when cursor is at "A" of "26 April 1564", di(will delete everything inside "()", i.e. deleting "bapt. 26 April 1564 - 23 April 1616".

To conclude, the operators and motions so far are listed in Tabs. 4.2 and 4.3. Notice that motions aw, as, ap are also given in the table. They are similar with their corresponding iw, is, ip except that when deleting, the consequent blank space (for word and sentence) or blank row (for paragraph) will also be deleted. (Notice that *Vim* marks the end of a sentence using ".", "?" or "!" followed by a blank space or tab or line, and the end of a paragraph by an empty row.)

To change a piece of text, operator **c** is used, followed by its associated motion to indicate the range of text to be changed. The same motions as given in Table 4.3 can be used. Effectively, operator **c** deletes/cut the text indicated by the motion first (just like operator **d**), then switch to insert mode.

To copy a piece of text of clipboard, use y (stands for "yank") followed by its associated motion to indicate the range of text. The motions also follow Table 4.3.

TABLE 4.3 Commonly used motions.

Motion	Description
h, 1	One character to the left or right.
j, k	One row to the up or down.
b, w	One word to the previous or next.
(,)	One sentence to the previous or next.
{,}	One paragraph to the previous or next.
iw, is, ip	inner-word, inner-sentence, inner-paragraph.
aw, as, ap	a word, a sentence, a paragraph (including the end blank).
i', i", i'	inner-quotation for different types of quotations.
i(, i<, i[, }	inner-block for different types of brackets.

To paste the text in the clipboard to the text at the cursor position, use p. No motion is required.

In addition to the motions given in Table 4.3, another commonly used method to navigate to a particular position if text is to "find by character". For example, consider the following row of text. The cursor is currently at letter "A".

ABCDEFG; HIJKLMN; OPQ; RST; UVW; XYZ

In normal mode, using f followed by a character will navigate the cursor to the nearest corresponding character that appears in the text. For example, fG will move the cursor to letter "G". Similarly, f; will move the cursor to the ";" between "G" and "H". Key in f; again and the cursor will move to ";" between "N" and "O". From here key in 2f: and the cursor will go to ";" between "T" and "U", as it is equivalent to typing f; twice.

Search in the Text

It is common that we want to search for a particular keywords or phrase, and highlight all of its appearances in the text. To make the searching result highlighted, add the following line to the user profile at *vimrc*.

```
set hlsearch
exec "nohlsearch"
set incsearch
set ignorecase
```

where "hlsearch" highlights all matching results in the text, and "incsearch" allows highlighting texts while keying in the word or phrase. Each time "hlsearch" is enabled, *Vim* will remember the keywords from the previous search and automatically hight them in the text, which can be confusing sometimes. The command exec "nohlsearch" (exec command in the user profile

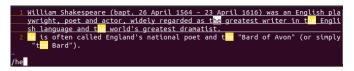

FIGURE 4.4

Search "he" in the piece of text of "William Shakespeare".

make *Vim* execute that command when starting a new session) that comes after set hlsearch resolves this issue by forcing *Vim* to clear its memory. Finally, "ignorecase" allows case insensitive while searching.

In normal mode, use /<keyword> to search keywords or phrase. With the above setup, search for "he" using /he will lead to the following result given in Fig. 4.4. From Fig. 4.4, it can be seen that all appearances of "he" (case insensitive) is highlighted, and the cursor is automatically moved to the first appearance, i.e. "he" in "and the world's greatest dramatist". Click Enter to quit searching. Now h, j, k and l can be used to navigate the cursor again, with the searching result maintain highlighted. Use n and N to navigate the cursor from the highlighted results. Notice that in this case, n and N can be used as motion together with delete/cut, change and copy as given in Table 4.2.

To disable the existing searching highlight, either start searching a new keyword, or key in command :nohlsearch in normal mode. For convenience, people may prefer to map it with a customized shortcut key as well, for example in *vimrc* key in

noremap <Space> :nohlsearch<CR>

so that Space can be used to clear the search highlights.

Visual Mode

The use of a mouse makes selecting a block of text very intuitive. As your eyes move across the text, you can start selecting at any specific character or row by click-and-hold the mouse key, and end selecting at any specific character or row by simply letting it go. The selected text will be highlighted, as if the cursor expands from one character to the entire block of text. You can then perform operations such as delete or copy of the selected block of text.

When using *Vim*, mouse is mostly useless. The visual mode of *Vim* provides users a similar experience when selecting a block of text almost as if using a mouse.
